

Work Experience Exercise

Summary

Build an API that will get data from a weather API and return the minimum, maximum, average temperature, and humidity for a given city and day.

Feel free to use an existing template project as a base to get started sooner. E.G.

<https://github.com/tiangolo/full-stack-fastapi-template>

<https://github.com/teamhide/fastapi-boilerplate>

Requirements:

- RESTful API to serve weather data (ideally Python / Fastapi)
- Create a GET endpoint to return the minimum, maximum, average temperature, and humidity for a given city and day from the openweather api
 - o <http://openweathermap.org/api>
- Create an API test to verify the minimum, maximum, and average temperature from the created RESTful API
- Use git for version control and publish on GitHub
- Unit tests (ideally using pytest)

Nice to have:

- Create a local database (e.g. sqlite / postgres) and cache the weather API into a weather table to avoid duplicate weather API calls
- Use Docker
- Use CI/CD
- Deploy this API
- Use infra as code
